Birth Control and STIs

Use birth control: http://www.youtube.com/watch?v=Fitxofd7kOA

Contraceptive Strategies

- 1. Prevent follicle development and ovulation
- 2. Prevent fertilization
 - Sterilization
 - Physical or Chemical Barrier
- 3. Prevent implantation

Uses estrogen and progesterone.

- 1. Birth Control Pill
- Synthetic Estrogen and Progesterone:
 - → inhibits GnRH...
 - → which inhibits FSH & LH...
 - → which **inhibits follicular growth and ovulation**

Must take at the same time every day

8% Failure Rate

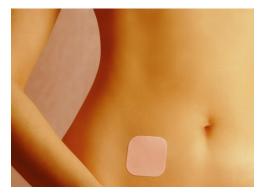

All use estrogen and progesterone.

2. The Patch

Replaced weekly

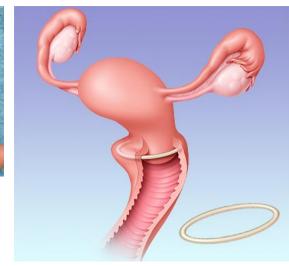

3. The Nuvaring

- a silicone ring worn inside the vagina that secretes hormones
- can take it out for up to 1 hour without losing effectiveness
- Replaced monthly

8% Failure Rate

Nuvaring: http://www.plannedparenthood.org/health-topics/birth-control/birth-control-vaginal-ring-nuvaring-4241.htm

4. Depo Provera – "The Shot"

a shot of hormones (high in progesterone) every 12
 weeks (3 months)

3% Failure Rate

5. Emergency Contraception Pill – ECP

- also known as "Plan B" and "morning after pill"
- can be taken up to 5 days after 'exposure' to sperm
- essentially, it is a high dose of estrogen and progesterone that:
 - prevents ovulation
 - prevents implantation
 - blocks fertilization
- average 75% effective the sooner it is taken,
 the more effective it will be
- The ECP is NOT the abortion pill it does not remove an implanted embryo from the uterus.

The morning after pill

6. Lactational amenorrhea method

is the use of breastfeeding as a contraceptive method. It is based on the physiologic effect of suckling to suppress ovulation by inhibiting menstrual hormones.

Many variables – therefore is not a reliable means of birth control

Preventing Fertilization: Sterilization

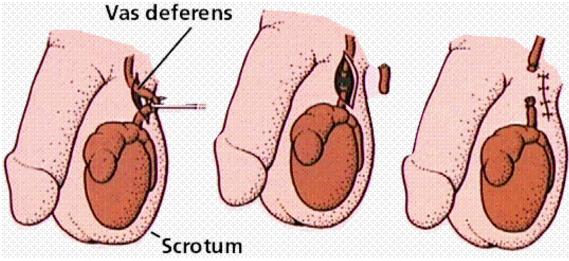

- a) Vasectomy: vas deferens is cut, sutured, cauterized, or clamped shut
- difficult to reverse
- can take 10-20
 ejaculations to clear all
 remaining sperm
- 1-2/1000 failures after 1 year

Vasectomy

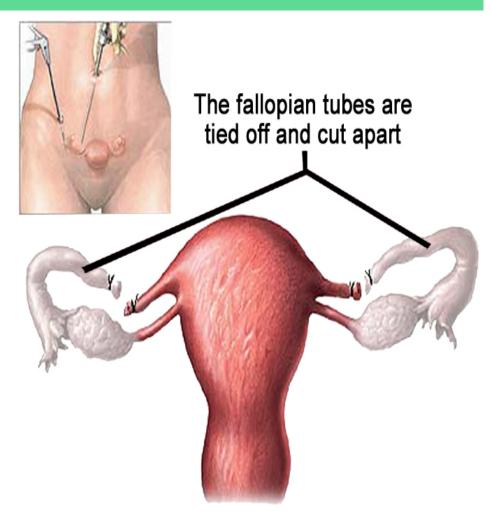

Vasectomy Link

Preventing Fertilization: Sterilization

- **b)Tubal Ligation: oviducts** are cut, cauterized, or clamped shut
- c) This has no effect on the menstrual cycle because the hormones move through the blood
- difficult to reverse
- failure rates: 5/1000 women after 1 year, 18/1000 women after 10 years

Preventing Fertilization: Sterilization

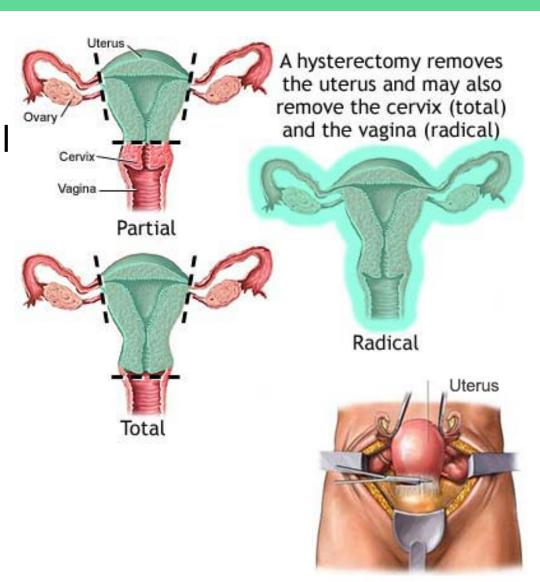

c) Castration: any surgical or chemical procedure where the female loses the ovaries and the male loses the testes

Castration may be done to treat prostate cancer. Androgens (male sex hormones) cause cancer cells to grow. Lowering androgen levels or stopping them from getting into prostate cancer cells often makes prostate cancers shrink or grow more slowly for a time. However, hormone therapy alone does not cure prostate cancer and eventually, it stops helping.

Preventing Fertilization: Hysterectomy

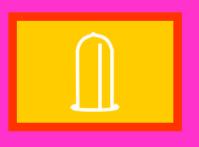

- **d) Hysterectomy**: surgical removal of the **uterus**
- Can be complete (removal of the entire uterus and cervix) or partial (cervix remains)

Sometimes recommended in severe cases of endometriosis, particular cases of reproductive system (uterine, cervical, ovarian) cancers

Preventing Fertilization: Physical & Chemical Barrier Methods

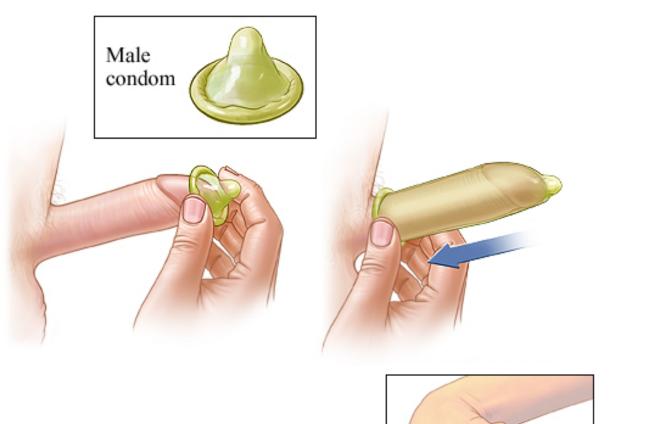

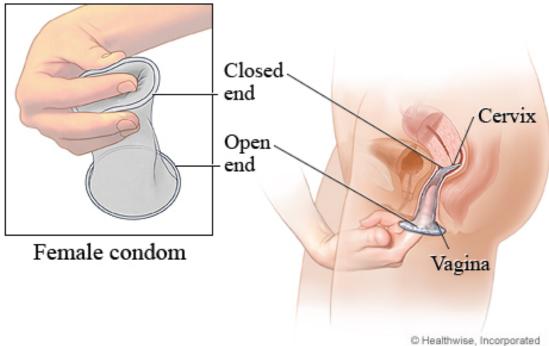

a) Condoms

- Sheath that acts as a barrier –
 prevents sperm entering
 female reproductive tract
- 86% effective must be put on before genital contact
- include male, female, polyurethane condoms and dental dams

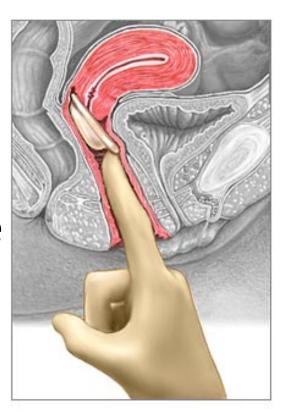

Preventing Fertilization: Physical & Chemical Barrier Methods

b) Diaphragm

- small cup filled with spermicide placed around cervix
- is both a barrier and chemical protection
- 80% effectiveness rate
- must be fitted & ordered by a doctor

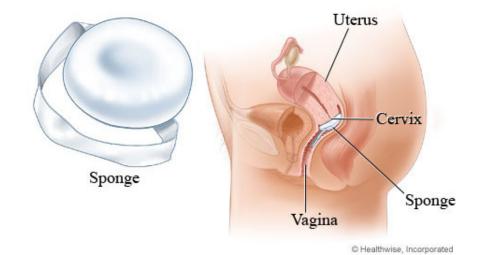

the uterus

Preventing Fertilization: Physical & Chemical Barrier Methods

c) Spermicides

- Contain the chemical Non-Oxynol-9
- May facilitate the spread of HIV and other STIs
- 80% (or less)
 effectiveness rate

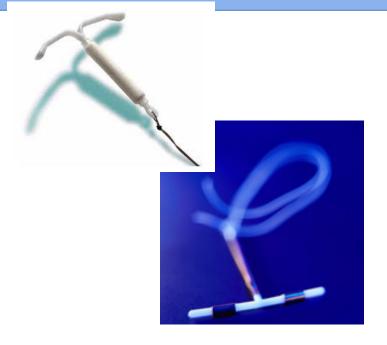

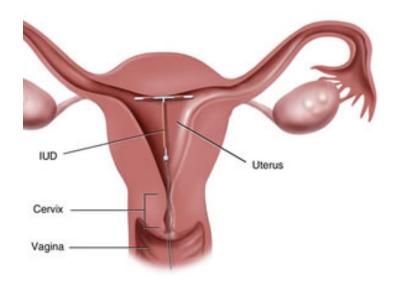

Killing Sperm

Intra-Uterine Device – IUD

- Small device placed in the uterus kills sperm
- Must be put in/removed by a doctor
- Can be worn for:
 - 5 years (hormonal) to 12 years (copper)
- Once removed, even after long term use, fertility returns to normal immediately.

Preventing Everything

ABSTINENCE – No sex or sexual contact.

0% Failure Rate

Sexually Transmitted Infections

Sexually transmitted infections are transmitted from one person to another primarily by contact of the genital organs during sexual activity.

~25% of people over 18 will contract an STI

Sexually Transmitted Infections

Can other animals get STI's? You Bet!

Atlantic bottlenose dolphins can get genital warts.

Syphilis is common in rabbits.

A. Bacterial Infections

1. Chlamydia & Gonorrhea (top 2 in your age group!)

- Untreated: causes pelvic inflammatory disease in women, or infertility (women & men)
- Causes scar tissue in fallopian tubes... and blockage affects fertility
- 80% females, 50-60% males have no symptoms
- Itching, discharge, burning during urination
- Treatment: antibiotics

A. Bacterial Infections

2. Syphilis

 Can spread across the placenta: brain damage, seizures & possibly death to the fetus

Treatment: antibiotics

B. Viral Infections

- No cure but many of the symptoms can be alleviated by medication
- Symptoms vary between viruses, but most have no symptoms
- If used consistently & correctly, <u>condoms</u> are can be highly effective in preventing most viral STIs

B. Viral Infections

- 1. HPV human papilloma virus genital warts
- Spread by skin-to-skin contact
- Warts can appear on genitals (look like cauliflower); many have no symptoms
- Linked with throat cancer, cervical cancer in women, penile cancer in men
- HPV vaccine available for girls and boys. Can be given up to age 26. Almost 100% effective.

Oral sex and throat cancer: Michael Douglas HPV report spotlights "epidemic"

B. Viral Infections

Herpes

- Spread by skin-to-skin contact; often no symptoms; sores on genitals & groin area
 - Women who acquire genital herpes during pregnancy can transmit the virus to their babies.
 - Untreated HSV infection in newborns can result in mental retardation and death.
 - Can ONLY be TREATED NOT CURED.

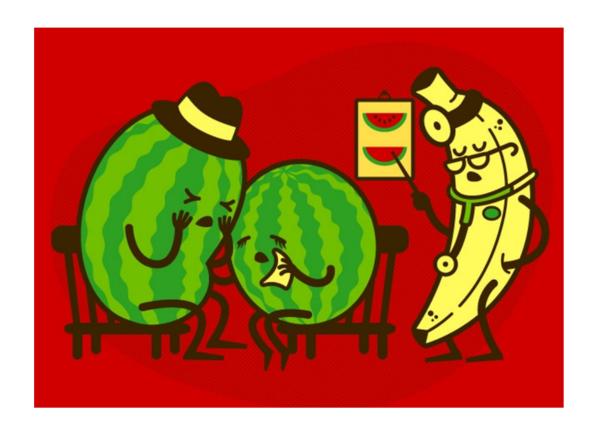

Birth Control Methods

- 1. Which birth control methods protect against STDs?
- 2. What is an IUD?
- 3. What is a diaphragm and how does it work?
- 4. State one difference between a female condom and a male condom.
- 5. What is lactational amenorrhea?
- 6. What is the difference between castration and hysterectomy?
- 7. State how the effectiveness of a condom or diaphragm can be improved and why.

Assistive Reproductive Technology

Assisted Reproductive Technology

Sterile: unable to have children

Assisted Reproductive Technology

Infertile: difficulty conceiving

- <u>Average</u> time to conceive = 6 months (longer if individuals are older than 25)
- After 1 year of regular unprotected sex, if a couple hasn't conceived, they are considered infertile

Possible Causes of Sterility/Infertility

Men

Blocked epididymus or vas deferens

risk factors: STIs

Low sperm count

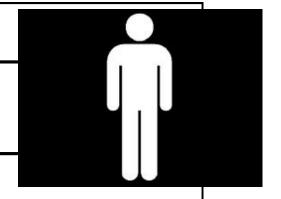

risk factors: overheated testicles, smoking, alcohol

High proportion of abnormal/non-viable sperm

 risk factors: overheated testicles, exposure to toxins or radiation, infections such as STIs

Impotence

 risk factors: vascular disease, nervous system injury, stress, hormonal imbalance, medication, smoking, alcohol

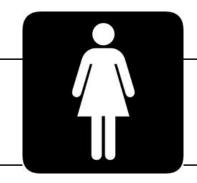

Possible Causes of Sterility/Infertility

Women

Blocked fallopian tubes

risk factors: STIs

Failure to ovulate

 risk factors: hormonal imbalances for many reasons, including malnourishment, stress

Damaged eggs

risk factors: exposure to toxins or radiation

Endometriosis

- condition where endometrial tissue grows outside uterus (can be painful)
- •risk factors: genetics, hormone imbalance, immune factors toxins (lots of debate)

Injected Sperm

Washed Sperm

1. Intrauterine Insemination (IUI)

- Sperm are collected and concentrated
 placed in uterus
- Sperm may be from woman's partner, or from another donor (sperm bank)

 Useful if: blocked vas deferens, low sperm count, or high proportion of

non-viable sperm

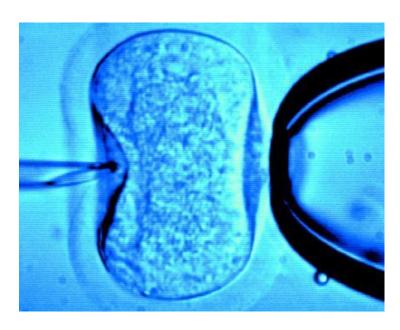

- 2. In Vitro Fertilization (IVF) "in glass fertilization"
- Eggs close to ovulation are removed from follicles
 - → sperm and egg are combined in Petri dish
 - → morula is placed in uterus

Useful if: oviducts are blocked, or in combination with

other technologies

In Vitro Fertilization

In Vitro Fertilization

3. Surrogacy

- Through IUI or IVF or both, infertile couple contribute gametes → baby is carried by another woman (surrogate mother)
- Useful if: pregnancy is impossible or dangerous to the health of a woman

4. Superovulation (Fertility Drugs)

- Hormone treatment stimulates production and ovulation of multiple eggs
- Often used in combination with other reproductive technologies
- Useful if: women rarely or never ovulates
